## A *Non-Sticky* Situation

A mass  $M$  undergoes projectile motion, where it is shot with speed  $v$  at an angle of  $\theta$  from the horizontal. It achieves a maximum height  $h$  and traverses a horizontal distance  $D$  from there to the ground. Now, let's assume a mass  $m$  is shot vertically upwards with speed  $v$  right below the maximum point of  $M$ 's trajectory. Mass  $m$  is shot in such a way that when  $M$  reaches its maximum height, the two masses collide completely elastically at that point. Then, mass  $M$  undergoes a second projectile traversing a horizontal distance  $x$  from the point of contact to the ground. You may ignore air friction for all the questions below.

1. If  $v_1$  and  $v_2$  are the vertical velocities of  $m$  and  $M$  after the collision, respectively, find the expressions for  $v_1$  and  $v_2$  both in terms of the variables  $m$ ,  $M$ ,  $v$ , and  $h$ . Then, find  $v_1$  and  $v_2$  both in terms of the variables  $m$ ,  $M$ ,  $v$ , and  $\theta$ .
2. If  $\alpha = \frac{m}{M}$ , find the expression for  $\frac{x}{D}$  in terms of  $\alpha$  and  $\theta$  only. In other words, find

$$f(\alpha, \theta) = \frac{x}{D}$$

3. If we call  $f(\alpha, \theta)$  the ratio function, solve for  $\alpha$  when  $\theta = \frac{\pi}{4}$  and the ratio function is equal to 2.
4. Find  $\alpha(\theta)$  for any angle when the ratio function is 2. For the ratio function to be equal to 2, find the maximum exclusive angle (the bound angle) in degrees that restricts  $\theta$  to  $0^\circ < \theta < \phi$ , where  $\phi$  is not necessarily  $90^\circ$ . Ultimately, this means that when  $\theta \geq \phi$ , we can never get the ratio function to equal to 2 for any  $\alpha$  value.
5. Find  $\alpha(\theta)$  for any angle when the ratio function is equal to a value  $c$ , where  $c > 1$ . For the ratio function to be equal to  $c$ , find the maximum exclusive angle (the bound angle) in degrees, as a function of  $c$ , such that it restricts  $\theta$  to  $0^\circ < \theta < \Phi(c)$ . Then, use a graphing calculator or an online tool to graph  $\Phi(c)$  for  $1 < c < 50$ . Ultimately, this function describes the exclusive upper bound of angle  $\theta$  that allows the ratio function to reach any  $c$  for some  $\alpha$  value.
6. If there is another mass  $m$  placed under  $M$ 's trajectory in the second projectile, also being shot vertically upwards at speed  $v$ , prove that  $0 < \alpha < 1$  is the only range of  $\alpha$  values that guarantees a second collision between  $M$  and  $m$ . Refer to the diagram below.
